

VRA 18: What are the risks of causing new outbreaks of FMD by staging organised sporting events (including running, cycling or canoeing events such as triathlons or marathons)?

1. SUMMARY OF OVERALL RISK

This risk assessment was compiled according to terms of reference provided by the Scottish Government regarding time of delivery, title of veterinary risk assessments (VRAs) and level of detail required. EPIC scientists created a generic framework suitable for the VRAs; collated and updated existing information on risks; filled gaps in the documents (including references where appropriate); and drafted new VRAs where necessary. These documents may require updating as new information becomes available or legislation develops, or if more in-depth assessment is necessary.

The purpose of this document is to qualitatively assess the risk of the specified activity in the face of an FMD outbreak in the UK. The assessment includes proposed actions to mitigate the risks associated with the specified activity, and which could form the basis of license conditions where necessary.

DEFINITIONS OF RISK LEVEL (OIE 2004, DEFRA 2011):

Negligible So rare that it does not merit consideration

Very low Very rare but cannot be excluded

Low Rare but could occur

Medium Occurs regularly

High Occurs very often

Very High: Events occur almost certainly

Overall risk: The risk of allowing the activity described is:

PΖ

RZ

With no mitigation measures

medium

medium low

low

With mitigation measures described

medium

low/medium

SZ

2. LEGISLATION, DEFINITIONS & ASSUMPTIONS

Statutory disease control requirements are applicable to livestock premises on suspicion and confirmation of FMD. When suspicion of disease cannot be ruled out, and diagnostic samples are taken, a Temporary Control Zone is put in place (TCZ) surrounding the suspect premises. On confirmation of disease, a national movement ban (NMB) is enforced by introducing a national Restricted Zone (RZ). A 3 km Protection Zone (PZ) and 10km Surveillance Zone (SZ) are implemented which place restrictions on movements and activities around infected premises to prevent spread of disease. Later in the outbreak, restrictions may be relaxed either through reducing the size of the RZ or through allowing some resumption of normal activities under licence within the RZ, SZ or PZ. In this VRA, RZ is used to refer to areas which are within the RZ, but do not also fall within the PZ or SZ.

In general, access to infected premises or premises under suspicion of infection is not permitted. Scottish Ministers can prohibit access to land within a PZ, including core paths (FMD (Scotland) Order 2006, article 35). Local authorities can close land for up to six days. In addition landowners can request closure of their land for longer periods - subject to a risk assessment AHVLA and local authorities can sanction closure and notify Scottish Ministers (Land Reform Act (Scotland) 2003, chapter 4, paragraph 11).

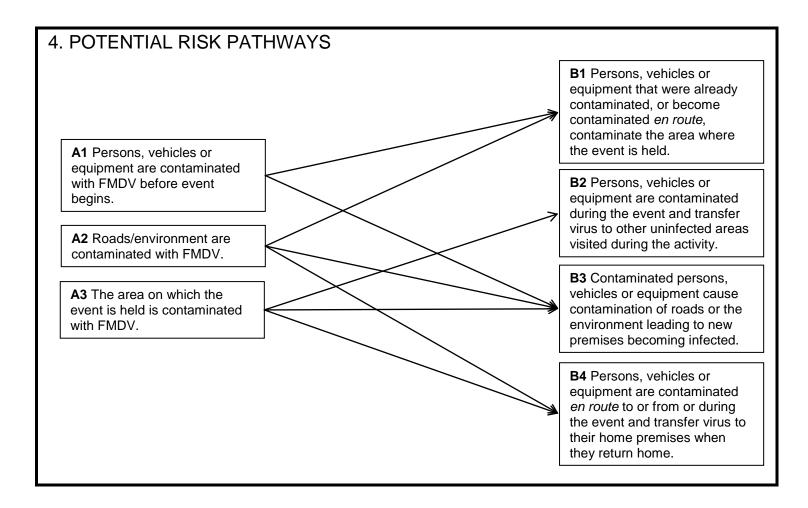

This risk assessment covers organised sporting events including running, cycling, canoeing, triathlon and similar events, but not equestrian events for which there are separate risk assessments.

In this VRA, the term 'agricultural land' or 'agricultural areas' refers to land that is being used or has been used for keeping livestock or other FMD-susceptible animals. It does not include arable land where no livestock have been present for an extended period of time.

Disinfectants must be approved for use by the Diseases of Animals (Approved Disinfectants) (Scotland) Order 2008 as amended and be used at the FMD Order dilution.

3. HAZARD IDENTIFICATION

- a) Hazard: FMD virus (FMDV)
- b) <u>Risk hypothesis</u>: During an FMD outbreak people attending or participating in events in the countryside may come into contact with FMDV or with susceptible livestock. There is a risk that FMDV will spread via people or other fomites and cause further disease outbreaks.

52EXPOSURE ASSESSMENT		
Factors which are likely to affect this probability of exposure are:	Comments and risk estimates if/where appropriate	
Infection source: A1 Persons, vehicles, dogs or equipment are contaminated with FMDV before event begins		

In general, risk of contamination is influenced by: • Proximity to a premises where FMD has been detected ("infected premises")	 Risk of transmission is highest adjacent or close to premises with FMD. Once a NMB is in place, most transmission occurs by local spread (<3k from a premises with FMD) (Gibbens et al. 2001, Keeling et al. 2001, Haydon et al. 2003). It is difficult to quantify relative risks associated with different transmission routes within local spread but indirect transmission via fomites and contamination of roads and environment around premises with FMD are likely to play an important role. Risk of airborne transmission decreases rapidly with distance from premises with FMD and is only likely to occur over significant distances if many infected animals (especially pigs) are present (Donaldson and Alexanderson 2001). In a PZ there are known infected premises which may be at varying stage of diagnosis, slaughter, cleansing and disinfection. The risk of local transmission from detected infected premises is medium. In a SZ, there are no detected infected premises. The smallest distance at which infected premises could be located would be 3km away. The risk of local transmission from detected infected premises is low. In a RZ, there are no detected infected premises. The smallest distance at which infected premises could be located is 10km so the risk of local transmission from detected infected premises. The smallest distance at which infected premises could be located is 10km so the risk of local transmission from detected infected premises.
Presence of animals with undetected or incubating FMD, or failure to report FMD	 In addition to premises where FMD has been detected ("infected premises"), there may be premises where FMD is present but has not yet been detected. Infected livestock may excrete FMDV for several days before the appearance of clinical signs, potentially leading to transmission or contamination prior to disease detection, particularly in cattle and pigs (Alexanderson et al. 2003, Orsel et al. 2009). FMD in sheep can be difficult to detect clinically as not all animals show clinical signs, and clinical signs are usually mild and short lived (Hughes et al. 2002). In addition, sheep may be inspected less frequently/ thoroughly. There is therefore a higher risk of undetected infection on sheep-only premises. The risk of undetected infection is highest in a PZ, followed by a SZ then a RZ. The risk of undetected premises with FMD arising from spread over longer distances can be better quantified by analysis of movement data to identify movements of animals from areas where FMD has been detected, before the NMB.
Stage of outbreak	 Early in the outbreak there is increased risk of undetected infection in all zones and lack of information on movements.
Likelihood of detection and transmission is influenced by FMD virus strain	There are 7 serotypes of FMDV: O, A, C, SAT1, SAT2, SAT3 and Asia 1. The different serotypes (and different strains within each serotype) have different characteristics for example in terms of host species susceptibility, length of incubation period, ease of detecting clinical signs and likelihood of air borne transmission (Kitching and Hughes 2002, Gloster et al. 2008). Much UK research is based on the 2001

	outbreak, which was caused by serotype O, strain PanAsia. However future outbreaks may involve other serotypes/strains and therefore present different epidemiological situations. On confirmation of FMD, the serotype and strain would be identified by The Pirbright Institute. This information would help to inform estimates of risk.
Specific risks: Likelihood that vehicles are contaminated	
Origin of vehicles	 The risk that vehicles are contaminated is influenced by the proximity of the home premises to premises with FMD, and the presence of susceptible livestock with undetected infection at the home premises, as above.
Movement history of vehicles	 Movement to other premises increases the probability of contamination.
Cleansing and disinfection of interior and exterior of vehicles	 FMDV is very sensitive to approved disinfectants and good biosecurity will reduce risk of virus transfer via fomites such as personnel, vehicles and equipment.
Length and duration of journey, number of stops en route and proximity of route to premises with FMD	 Longer journeys, multiple stops and proximity to premises with FMD increase risk that vehicles become contaminated en route.
Likelihood that people are contaminated (organisers, ma	rshals, participants, spectators)
Recent contact with infected livestock	 Risk is greatest if people have had contact with infected animals, and next greatest if they have been to premises with FMD. The likelihood and amount of contamination varies with species, stage of infection, degree of contact and cleansing and disinfection.
Occupation	Likelihood and amount of contamination increases with potential occupational exposure to FMD (e.g. farmer, vet).
Cleansing and disinfection prior to arrival	Risk of contamination decreases if clean clothing worn and cleansing and disinfection of outerwear has been undertaken.
Presence of other non-susceptible animals	 People may also bring dogs, which may be contaminated with FMDV. The likelihood of contamination is similar to people and will be highest if dogs have had access to infected livestock.
Likelihood that equipment is contaminated	
Previous use in contaminated areas without cleansing and disinfection	 There is a risk of transmission through equipment such as bicycles or boats that have been used in other areas and become contaminated.
Infection source: A2 Roads/environment are contaminated with FMDV	
 Proximity to premises with FMD, presence of undetected or incubating infection, stage of outbreak, strain differences 	Roads close to premises with FMD represent the highest risk.
Infection source: A3 The area on which the event is held	is contaminated with FMDV
Proximity to premises with FMD, extent and timing of movements of susceptible animals from or close to premises with FMD and stage of outbreak	See A1.
Presence and density of susceptible livestock at the location where the event is held	 The risk that the environment is contaminated is greatest if livestock with undetected infection are present in the area. Since FMDV can survive in the environment, risk is also increased if the area has been used for grazing livestock within the last month (longer if cold weather).
Level of use of land where event is held	 The risk that the environment is contaminated increases with increasing level of use.

	role in FMD transmission (Ward <i>et al.</i> 2007).	
•	All British deer species are susceptible to infection and can transmit virus to domestic livestock experimentally (Gibbs <i>et al.</i> 1975). Wild boar are also susceptible	
•	(Elbers et al. 2003, Hartley 2010). However in Western Europe post-outbreak serosurveys and diagnostic testing of animals with suspicious clinical signs have never revealed positive animals (Elbers et al. 2003, Mouchantat et al. 2005) and there is no evidence that deer or boar have played a role in FMDV spread in UK. The density of wild boar in the UK at present is likely to be too low for boar to be of importance in transmission (Hartley 2010). The risk of disease spread through infected deer or wild boar is therefore negligible, but this risk could change if ecological factors change, such as deer and boar densities or contact patterns. Ideally risks should be assessed using up-to-date information for a specific location. Other species can be infected, such as hedgehogs, but are unlikely to be important in transmission. Wildlife can also move FMDV mechanically if they become contaminated (for example scavengers such as seagulls, crows or foxes).	
•	Overall, the risks of further spread of FMDV associated with wildlife are very low but any activity which causes disturbance to wildlife does increase this risk, especially close to premises with FMD.	
	Favourable conditions will increase the probability of survival and thus probability of contamination being present. FMD can survive on pasture for a few days in hot weather, and up to 2 to 3 months in bovine faeces at 4°C. Survival duration increases with decreasing temperatures, increasing relative humidity and presence of organic material and varies with virus strain (reviewed by Bartley <i>et al.</i> 2002).	
Risk of transmission: B1 Persons, vehicles, dogs or equipment that were already contaminated, or become contaminated en route, contaminate the area where the event is being held		
Contact between vehicles and susceptible livestock	Movement of vehicles onto land where susceptible livestock are or will be present increases the risk of transmission if vehicles are contaminated. This can be reduced by ensuring cars are parked on hard standing in areas that susceptible livestock do not access. Cleansing and disinfection of wheels and undercarriage can eliminate the risk if done properly. This requires facilities but may be appropriate depending on the level of risk and size of the event.	
Total numbers of people involved	Higher numbers increase the risk that some will be contaminated.	
Number of contaminated personnel and vehicles	Increasing numbers increases the total probable amount of FMDV that would be released, if present	
Proximity of the area where the event is held to susceptible livestock	The greatest risks are associated with the presence of susceptible livestock in the area where the event is being held. Susceptible livestock on adjacent premises are also at	

Contact between people and susceptible livestock Distance covered Unrestrained dogs Cleansing and disinfection on arrival at the event	 increased risk. Since FMDV can survive in the environment, there are also risks for livestock which are later moved onto to an area where contamination has been introduced. If the activity is taking place in areas which are not agricultural land and are never used for grazing susceptible livestock or growing feed or bedding for susceptible livestock, the risks are negligible. Any potential contact with susceptible livestock increases the risk of transmission. The risk can be reduced by ensuring that people only have access to limited areas, maintaining good perimeter security and ensuring any event routes are clearly marked. The likelihood and amount of contamination released increases with the distance covered by the event. Organised sporting events may cover very long distances, increasing the risk that clean areas could become contaminated. If dogs have access to susceptible livestock, or by covering larger distances are able to access contaminated areas, there is an increased risk that they will contaminate an area with FMDV or become contaminated. Dogs may also disturb wildlife, increasing the risk of virus dissemination by infected or contaminated wildlife. FMDV is very sensitive to approved disinfectants and good biosecurity will reduce risk of virus transfer via fomites such as personnel, vehicles and equipment. Disinfectant foot baths can be effective at reducing
	 Disinfectant foot baths can be effective at reducing contamination, as long as foot wear are also cleaned
	and disinfectant is regularly replenished.
Risk of transmission: B2 Persons, vehicles or equipment other uninfected areas visited during the activity	nt are contaminated during activity and transfer virus to
Contact with infected livestock or contaminated areas, number of people, size of group	• See B1.
Distance covered, number of premises covered	See B1 plus if the event takes place on land comprising more than one premises, there is an increased risk of transferring FMD between premises.
Risk of transmission: B3 Contaminated persons, vehicle environment leading to new premises becoming infected	es or equipment may cause contamination of roads or the
Failure to disinfect vehicle, personnel and equipment before outgoing and return journey	Appropriate cleansing and disinfection reduce risk of contamination.
Length and duration of journey, number of stops en route and proximity of route to susceptible animals	 Longer journeys and multiple stops increase risk of contaminating roads or environment. Proximity to high densities of susceptible animals increases risk of disease outbreak if contamination does occur.
Risk of transmission: B4 Persons, vehicles or equipment their home premises when they return home	t are contaminated during activity and transfer FMDV to
Presence of susceptible livestock at home premises	Direct or indirect contact with susceptible livestock provides opportunity for transmission, if contamination is present.
 Failure to disinfect vehicles, personnel and equipment before entering the home premise 	Appropriate cleansing and disinfection reduce risk of contamination.

6. CONSEQUENCE ASSESSMENT

Spread of FMD to uninfected premises.

7. RISK MANAGEMENT OPTIONS

The movement of personnel and spectators (& other non-susceptible animals) to and from events on agricultural land does carry a risk of spreading FMD to uninfected farms due to contamination of roads and environment. Indirect transmission of FMDV via fomites is an important source of infection, and any vehicles, people, equipment etc. which come into contact with FMDV risk passing disease to any livestock they come into contact with. However there is little information on the real importance of countryside access in FMD spread, meaning it is difficult to quantify this risk accurately. The risks associated with access to the countryside during an FMD outbreak are predominantly influenced by the likelihood that people or other fomites will already be contaminated or that they will come into contact with contaminated land or infected but undiagnosed livestock whilst in the countryside. The highest risks are therefore associated with people who have had contact with infected livestock, or people who come into contact with livestock or livestock grazing areas at the event. The risks are higher in the PZ and to a lesser extent to SZ, since there are likely to be undetected premises with FMD, and people and other fomites are more likely to have come into contact with infected livestock.

Potential risk management options:

- (i) Do not permit events to be staged.
- (ii) Permit staging of events but not in the very early stage of an outbreak, ie only after day 8.
- (iii) Permit staging of events from the early stages of an outbreak under certain conditions such as:
 - a) Confine events to non-agricultural land until FMD has been eradicated.
 - b) Allow events only on agricultural holdings where there are no susceptible livestock.
 - c) Allow events on holdings with livestock, but take precautions to limit the risk.

Although option (i) is the lowest risk option, it is also the most costly to local economies and unlikely to be necessary in areas where the risks of premises with FMD are low. In the early stage of an outbreak there is a higher risk of undetected premises with FMD in all zones so option (ii) is preferred to option (iii).

The risk is:

PZ SZ RZ
With no mitigation measures medium medium low
With mitigation measures below medium low/medium low

These risk levels were assigned based on scientific literature available and expert opinion where appropriate by considering the risk pathways and the factors affecting each risk pathway, as listed in sections 4 and 5.

8. SUGGESTED RISK MITIGATION MEASURES

The risk levels given in section 7 assume that the follow risk mitigation measures are followed:

- (i) An event held on agricultural land should be approved by the AHVLA office responsible for the area, to whom an application must be made in writing.
- (ii) Participants should not have visited an infected premises or any premises within the PZ where susceptible livestock are kept within the past 7 days.
- (iii) Start activity wearing clean footwear and clothing.
- (iv) Ensure any equipment is clean before starting activity.
- (v) Park vehicles on areas of hard standing and avoid any contact between vehicles and farmland and areas where livestock are present.
- (vi) Do not approach, and never touch or handle, livestock.
- (vii) Do not walk/cycle with dogs, even on a lead, where there may be cattle (because cattle are curious and approach dogs, and it may then be impossible to avoid contact with them).

- (viii) For parts of the event which involve large numbers of people and vehicles such as start and end points and shorter routes, agricultural land should be avoided as far as possible. If events are held on agricultural land:
- (a) Ensure that susceptible livestock are not present on land used. If the land has been grazed by sheep or cattle, it should not be used for an event for at least 28 days after the last animal was removed, and the land should be kept free of livestock for at least 28 days thereafter;
- (b) Ensure the area is surrounded by a perimeter fence which will prevent contact between non-susceptible animals and people attending the event and any susceptible livestock present in fields surrounding the area used by the event;
- (c) Entry for vehicles must be by a designated disinfection point, where cleaning and disinfection should be carried out under supervision. Approved disinfectants must be used at the correct concentration. This must be followed in a SZ. In a RZ where susceptible livestock are excluded for 28 days before and after the event this could be relaxed;
- (d) Pedestrian entrances for personnel and spectators must be via an approved disinfectant footbath or pad. This must be followed in a SZ. In a RZ where susceptible livestock are excluded for 28 days before and after the event this could be relaxed.

(ix)For routes which cover longer distances, choose routes which avoid farmland and areas where livestock are present (this should be followed at all times in the SZ, and followed where possible in the RZ).
